

WebLinked user guide

WebLinked **turns a URL into a broadcast signal**. One binary takes a web page and produces a proper video output at the raster and rate you specify — SDI on a DeckLink or AJA card, NDI and OMT on the network, and a fullscreen GPU window — all from the same pipeline, at the same time.

It is for someone who already knows what 1080p50 means and has a vision mixer to plug into. It does not try to hide the broadcast decisions from you.

What's proven, and what isn't. WebLinked has been **run on a live event**. NDI is verified end to end against a real receiver, alpha included. SDI is measured against a real DeckLink Duo 2, with colour confirmed by loopback capture against an independent BT.709 reference.

Not everything: **the SDI key channel itself, audio over SDI and genlock over hours are unmeasured**, and **AJA and OMT compile against their SDKs and have never met hardware or a receiver**. The fullscreen output's Windows and Linux backends are written and have never been run. [04-verification.md](#) gives the numbers and the method rather than a promise.

What it is not

- **Not a media server.** No playlist, no layers, no compositing, no transitions. It renders one page. Two graphics at once is a job for the page.
- **Not a capture tool.** Output only.
- **Not genlocked.** The engine's clock is a software clock; an SDI card's scheduled playback absorbs the difference. [01-architecture.md](#) says which number in `/api/state` tells you it is going wrong.
- **Not a replacement for CasparCG** if you already run CasparCG.

Running it

WebLinked **has no window of its own**. It is a render host and a control server; the control page it serves is the entire UI. Open it in any browser, or click the WebLinked icon in your menu bar (macOS) or notification area (Windows and Linux) and choose **Open control page**.

Double-click it and it opens the control page in your default browser once the server is up — a launch with no arguments at all is taken as "show me something". Type a command line and it stays quiet, because you asked for something specific; `--open` and `--no-open` decide it explicitly.

There is **one download** per platform. Earlier versions offered a second, a *desktop app* that wrapped the engine in a separate tray launcher; the engine now puts its own icon in the menu bar or notification area, so that wrapper was retired in v1.0.0.

```
WebLinked --url https://example.com --format 1080p50 --ndi=Test --headless
```

Then open <http://127.0.0.1:7654/>. `--help` lists every flag *and which backends this build actually contains*, which is the quickest way to find out whether your download has SDI in it.

Downloads bundle the NDI runtime, so NDI works on a machine that never installed the SDK. **The hosted builders have no DeckLink or AJA SDK**, so **SDI output needs a local build** — see [02-building.md](#).

The control page

The preview is itself an output, fed by the same pipeline as everything else — which is the point: **if the preview is right, the outputs are right**. The red note under it says so plainly: *this is the on-air output*.

The preview is interactive. Clicks, scrolling and typing go to the live page — enough to dismiss a cookie banner or sign in. A link that asks for a new tab loads *here* rather than opening a window.

Several sources run as tabs. Each is a whole pipeline with its own browser, clock, raster and outputs, so one hung page cannot touch the others.

The pacing panel is the health readout

Field	What it tells you
ticks	Frames the clock has asked for
repeated frames	The page didn't paint in time, so the last frame went out again
dropped ticks	The pipeline missed a frame slot entirely — the number to watch
last lateness	How late the most recent frame was
paints	How often the page actually rendered
under / over	Audio buffer starvation and overflow

A page that only repaints on data change will show a high repeated-frame count and be perfectly healthy. **Dropped ticks are the ones that mean something is wrong.**

Outputs

WEBLINKED v0.4.0 CONTROL **SETTINGS** DIAGNOSTICS

site 1920x1080p50

clock 1920x1080p50

+ source

OUTPUTS

preview

Kind: preview Name: preview

Preview scale (1/n): 4

Apply Remove

WebLinkedShots

Kind: ndi Name: WebLinkedShots

☐ Carry alpha (BGRA, straight)

Apply Remove

Add an output

Changes apply immediately. An output that cannot open keeps its previous settings and shows why – nothing is silently dropped.

SAVED SETTINGS

/Users/allansargeant/Library/Application Support/WebLinked/settings.json (not saved yet)

Save Reload from file

Saving records what is actually running, so a card that failed to open is never written down as working. Anything given on the command line wins over the file at the next launch.

SOURCE

URL: https://github.com

Format: 1920x1080p50 Colour matrix: auto (709 at 720+ lines)

Pacing: external – we drive frames New tabs and windows: load here instead

☒ Arm the preview for input when the page loads

Apply Remove this source

Changing the format or the pacing restarts things: every output reopens at the new raster, and a pacing change rebuilds the browser at the same URL. Neither is a mid-show operation.

Each output editor shows **only the fields that backend really has** — an NDI sender gets a name and an alpha checkbox, a DeckLink gets a device index and keying, the preview gets a scale factor. Offering a DeckLink keying mode on an NDI output would invite you to set something that is then silently ignored.

Background is on every output, because it is not a backend setting — the engine composites before a frame reaches a backend:

- **Transparent** keeps the page's own alpha, for a keyed SDI fill or an NDI feed with alpha.
- **A colour** composites the page over it and leaves the frame fully opaque, for a switcher that only has a chroma keyer.

Changing it does not restart the output.

Apply replaces an output in place rather than removing and re-adding it. If the new settings cannot open — a card already claimed, an NDI name in use — **the previous output is restarted** and the reason is shown. Renaming an output cannot leave you with no output.

Settings, and what wins

```
macOS    ~/Library/Application Support/WebLinked/settings.json
Windows  %APPDATA%\WebLinked\settings.json
Linux    $XDG_CONFIG_HOME/WebLinked/settings.json, else ~/.config/WebLinked/
```

Override with `--settings <file>` or `$WEBLINKED_SETTINGS` ; `--no-settings` ignores it entirely.
The command line always beats the file.

The settings file is deliberately *not* in the log directory — logs are disposable, settings are not.

Control from a show

Two protocols, the same verbs: **HTTP** for the control page and scripting, **OSC** for a Companion button or a show-control cue. A graphic that can only be changed by someone with a browser open is no use in a running show.

Security. The HTTP server binds `127.0.0.1:7654` with **no authentication by default**. If you bind it to a network interface (`--bind 0.0.0.0`), **set** `--token` — anyone who can reach the port can change what is on air. There is **no TLS**: put it behind a reverse proxy or keep it on a trusted show network.

OSC has no authentication at all — that is the protocol, not a choice made here. It listens on `0.0.0.0:7655` ; `--no-osc` disables it.

Full verb list in [03-control-api.md](#).

When something is wrong

The screenshot shows the WebLinked application interface. At the top, there are tabs for 'WEBLINKED v0.4.0', 'CONTROL', 'SETTINGS', and 'DIAGNOSTICS'. Below these are buttons for 'site', 'clock', and '+ source'. The 'LOG' section on the left displays a series of INFO messages from 2026-07-31T11:31:53Z, detailing the application's startup process, including context initialization, browser opening, and engine starting. To the right of the log is a 'COLLECT' section with buttons for 'Download a bundle' and 'Write a report', followed by a description of a bundle. Below that is a 'WHERE THINGS ARE' section listing file paths for log, directory, and settings. At the bottom right is a 'BROWSER' section showing statistics like 'popups intercepted', 'popup policy', 'last popup', 'console errors', 'last console error', 'paints', and 'version'.

COLLECT

[Download a bundle](#) [Write a report](#)

A bundle is one JSON file carrying the build identity, the platform, the redacted configuration, the recent log and any crash reports sitting beside it. It downloads here rather than only naming a path, because the machine with the fault is usually not the one you are sitting at.

WHERE THINGS ARE

log file	/var/folders/27/hrb70lxx3n324fb14xx6jhx8000gn/T/tmp.tti3p5tK08/logs/WebLinked.log
directory	/var/folders/27/hrb70lxx3n324fb14xx6jhx8000gn/T/tmp.tti3p5tK08/logs
settings	/Users/allansargeant/Library/Application Support/WebLinked/settings.json

BROWSER

popups intercepted	0
popup policy	navigate
last popup	—
console errors	0
last console error	—
paints	36
version	0.4.0

The log lives at `~/Library/Logs/WebLinked/WebLinked.log` (or `$WEBLINKED_LOG_DIR`), and `WEBLINKED_LOG=debug` raises the level.

The app's own counters only prove it *sent* something. To check what actually arrived, the repo ships two independent receivers — `tools/ndi_probe.cpp` and `tools/sdi_probe.mm` — each carrying its own BT.709 reference, so a check is not a restatement of the code under test.

```
./ndi_probe --source Test --frames 100 --bars
```

Troubleshooting

Symptom	Cause
Control page sits on "connecting"	The page has no build step, so one syntax error kills every line after it. If it looks dead, that is the first suspect.
No SDI options anywhere	Your build has no DeckLink/AJA SDK. <code>--help</code> lists the backends this binary contains; SDI needs a local build.
High repeated-frame count	Usually fine — the page simply isn't repainting. Watch dropped ticks instead.
Dropped ticks climbing	The pipeline is missing frame slots. Check page complexity, raster and CPU.
Alpha looks wrong on SDI key/fill	Straight alpha is measured on SDI; the key channel itself is not yet measured. Verify on your own hardware.
Output opened, then reverted to the old one	Apply failed — a card already claimed or an NDI name in use — and the previous output was restarted. The reason is shown.
A new tab opened a window instead of loading	Shouldn't happen: no browser here owns a window, and popups are always cancelled into the same view.
Colour looks off	Check the colour matrix against the raster. Verify with <code>ndi_probe --bars</code> rather than by eye.
